

Moving layers and graded damage coupling with elasto-plasticity

Claude Stolz,

The paper investigate the coupling between graded damage [?] and elasto-plasticity. The elastic properties \mathbb{C} of the material depends on a damage variable d , then the free energy w depends on the strain ε , on internal variables α and on damage d : $w(\varepsilon, \alpha, d)$. Damage variable is bounded and its gradient is bounded by a concave function $f(d)$ in order to limit its concentration:

$$g_2(d) = \|\nabla d\| - f(d) \leq 0, \quad f(0) > 0.$$

These two conditions are taken into account by two Lagrange multipliers μ_i

$$\mu_i \geq 0, \quad g_1 = d(d-1) \leq 0, \quad g_2 \leq 0, \\ \mu_1 g_1(d) + \mu_2 g_2(d) = 0.$$

Introducing the potential energy \mathcal{E} of a body Ω submitted to prescribed displacement on $\partial\Omega_u$ and tension on the complementary part $\partial\Omega_T$.

$$\mathcal{E}(u, \alpha, d, \mu_i) = \int_{\Omega} w(\varepsilon(u), \alpha, d) d\Omega + \int_{\Omega} \mu_i g_i(d) d\Omega - \int_{\partial\Omega_t} \mathbf{T}^d \cdot u dS$$

The evolution of the internal parameter (α, d) are given by normality laws

$$\dot{\alpha} = \lambda \frac{\partial \Phi}{\partial A}, \lambda \geq 0, \Phi(A) \leq 0, \lambda \Phi = 0 \quad \dot{d} \geq 0, Y - Y_c \leq 0, \dot{d}(Y - Y_c) = 0$$

where Φ is a convex function of the thermodynamical force A associated to α : $A = -\frac{\partial \mathcal{E}}{\partial \alpha}$, and Y_c is a critical value for local fracture, Y is the release rate of energy associated to damage evolution, $Y = -\frac{\partial \mathcal{E}}{\partial d}$. The variations of potential energy gives the driven forces:

$$A = -\frac{\partial w}{\partial \alpha}, \quad Y = -\frac{\partial w}{\partial d} + \frac{1}{f} \operatorname{div}(\mu_2 \nabla d) + \mu_1(1-2d)$$

Variations of potential energy exhibit discontinuities along the boundary between sound and damaged material, this fact must be discuss.

In particular, w can be discontinuous along moving boundaries, especially along the surface where $d = 0^+$. If such a discontinuity exists additional dissipation occurs, if not this imposes some continuity conditions on the internal variable α . In this case, in the damaged zone plasticity and damage cannot evolve simultaneously as shown in [?].

This fact is illustrated on analytical examples based on cylindrical or spherical geometries on elasto-plasticity with or without linear hardening.
